

# MicroPulse — Today Page Guide

## Reading the morning coach dashboard

MicroPulse Performance Intelligence Platform

April 2026

### Table of Contents

## 1. What this page tells you

The Today page (/coach, the default landing screen after login) is the single most important screen in MicroPulse. It is built around the question: **“Who needs me to do something today, and what?”**

Every other page in MicroPulse — Quadrant, Decel Intelligence, Indoor Load, Injuries — feeds signals into the verdict you see here. If you only have five minutes in the morning, you read this page; everything else is for going deeper on individual players.

The page has four major sections, in the order they appear top to bottom:

1. **Decision Summary card** — per-player verdicts (RED / YELLOW / GREEN) for today
2. **Daily Briefing card** — team-level read in plain language
3. **Today Command Center** — squad availability tiles + day-state diagnostic
4. **Team Indoor Briefing** — appears only if your team has indoor sessions or active injuries

Plus, depending on data, you may also see a **Verdict Accuracy** widget (calibration), and a row of **navigation tabs** (Squad / Load / GPS / MD / Drills / Volatility / VALD / Strength / Trend / RTP) for going deeper.

---

## 2. The Decision Summary card

This is the most important block on the page. Each row is one player, with a single verdict flag at the right and a stack of diagnostic chips underneath.

### 2.1 Reading a player row

Each row has, top to bottom:

- **Player name + flag pill** — GREEN / YELLOW / RED. The flag is the system's overall recommendation: train normally, modify, or rest.
- **Wellness chips** — Sleep, Soreness, Fatigue, plus Wellness composite. Coloured red when *below the player's personal baseline* (not just below an absolute team threshold). A player who normally rates 4/5 on sleep but scored 3 today gets a red chip even though 3 isn't objectively low.
- **Load signals block** — yesterday's GPS (distance, sprints), the composite load score, NBS (Neuromuscular Burden Score), ACWR, and the McBurnie verdict. Each is a chip with its own color.
- **Indoor block** (when present) — composite indoor load, ACWR for indoor sessions, sessions-in-last-7-days. Only appears if the player has recent indoor data.
- **Decel Intelligence block** (when present) — overall decel flag plus a 5-dimension summary. Click through to the Decel Intelligence page for the full breakdown.
- **Injury block** (when active) — body part, RTP stage (e.g. "Sub-acute", "Sport-specific", "Return-to-play"), estimated return date.
- **Counterfactual hints** — short "what if" sentences like "If HRV had been +15, would be GREEN". These tell you what the player needs to change to get a different verdict tomorrow.

## 2.2 What drives the overall flag

The flag is the result of combining all the above signals through the decision engine. The high-level rules:

- **RED** — the engine is confident this player should not train at full intensity today. Triggers when at least one strong signal is hard-flagged (e.g. ACWR > 1.5, McBurnie RED on multiple dimensions, wellness composite >2 SD below personal baseline, or active injury with no clearance).
- **YELLOW** — modify rather than skip. Triggers when several signals are amber, or one strong signal is amber, or the player's verdict yesterday was already YELLOW and signals haven't recovered.
- **GREEN** — clear to train normally.

The verdict is not a single threshold — it weighs all signals and accounts for the player's personal baseline. This is why the same wellness score can produce different verdicts for different players.

## 2.3 Override-aware verdict explanation

If the wellness self-report contradicts what the load data says (player feels fine but external signals say otherwise, or vice versa), the verdict explanation will surface that conflict explicitly. For example: "*Wellness GREEN but composite load is high — watching for tomorrow.*"

These are the most useful verdicts to read carefully — the disagreement between the two sources is exactly where coach judgment matters most.

---

### 3. The Daily Briefing card

A plain-language paragraph summary of the squad. Looks something like:

*“14 ready, 3 monitor, 1 at risk. 2 RPE check-ins missing (Jónatan, Bjarki). Yesterday was MD-3, today is MD-2 — moderate intensity recommended.”*

Use this as the line you take into the staff meeting. It is purposely written for a non-data-literate listener (head coach, club director). The key reader is the human who needs the answer in one sentence.

The card also lists **Top concerns** — a 3–5 player list with the single most important reason each is flagged. A typical entry:

*“Jónatan — RED — Spike on indoor composite (+1.8 SD) AND elevated ACWR (1.62)”*

Each entry links through to the player’s full row in the Decision Summary above.

---

### 4. Today Command Center

A block of status tiles giving you the team-wide squad availability picture at a glance.

#### 4.1 The header band

A team outlook indicator: **Normal**, **Caution**, or **High alert**. Driven by the proportion of red verdicts in the squad.

#### 4.2 The 6 status tiles

- **Full** — number of players cleared for full training
- **Reduced** — players with a YELLOW verdict that warrants modification
- **Recovery** — players who should rest or do recovery-only work
- **Dominant fatigue** — what the team-wide fatigue signature is (mechanical / metabolic / mixed)
- **Neural load** — the team-wide neuromuscular state from VALD + decel data
- **Next-day risk** — forecast of how today’s load will affect tomorrow’s verdict (from the Forecast model)

#### 4.3 The 4 compact intelligence tiles

- **Volatility %** — what fraction of the squad has unstable wellness over the last 7 days. High volatility means the squad is unsettled (often before an away trip, after a tough match, etc.)

- **Avg risk score** — team-average risk score. Useful for tracking trajectory week over week.
- **Protected / adjusted** — how many players are currently on either an injury override or a coach-imposed modification.
- **Baseline maturity** — how many of your players have a fully-mature 28-day personal baseline yet (relevant for newly onboarded squads).

#### 4.4 The coach recommendation box

A single sentence at the bottom of the command center, written like a head-coach handoff:

*“Squad is in normal range. Most signals settled. Watch Jónatan (decel concentration spike). MD+1 calls for moderate volume — protect Bjarki’s groin work.”*

This is generated from the cumulative signals across the page. Treat it as a starting point for discussion, not a directive.

#### 4.5 PDF export buttons

Two buttons at the bottom:

- **Readiness Risk** — exports the current verdict picture as a printable PDF for the medical team / head coach
  - **Post-Training** — generates the post-session summary report after training is logged
- 

### 5. Team Indoor Briefing (conditional)

This card appears below the command center **only if** your team has recent indoor sessions OR has any active injuries. For outdoor-only squads in good health it does not render at all.

When present, it gives you:

- A team-wide indoor readiness sentence
- Per-player indoor flags for anyone with elevated indoor composite or active injury
- Indoor-specific top concerns

For a deeper dive into indoor load specifically, click through to Monitoring → Indoor Load (its own dedicated guide).

---

### 6. Verdict Accuracy widget

Appears once your team has accumulated 30+ verdict-decision pairs (typically after 4–6 weeks of use). Shows two numbers:

- **30-day accuracy %** — how often the verdict matched what actually happened (player trained well = correct GREEN, player got injured / sick = correct RED, etc.)
- **Calibration slope** — whether the verdicts are systematically over-confident or under-confident

Use this as a long-running self-check. A team with accuracy stuck at 60% for months means either the personal baselines need recalibration (rare) or the coach is consistently overriding correct verdicts (common — talk it through with your performance lead).

---

## 7. The tab navigation row

The Today page is the first of several tabs across the top of the dashboard. Each tab is a deeper view:

- **Today** — this page
- **Squad** — full roster with availability + status detail per player
- **Load** — external load analytics (GPS/sprint distance/PL, comparable across windows)
- **GPS** — detailed per-player GPS view, browsable by date
- **MD** — microcycle planner (week setup, MD-day assignment)
- **Drills** — training session library + assignment
- **Volatility** — readiness variance tracking (which players are most/least stable)
- **VALD** — strength tests (Nordbord eccentric strength, ForceFrame groin/hip, ForceDecks CMJ)
- **Strength** — VBT (velocity-based training) fatigue per exercise
- **Trend** — historical readiness trend across the season
- **RTP** — return-to-play rehab templates

Most coaches live on Today + Squad + GPS day-to-day, with the deeper tabs visited weekly for planning.

---

## 8. Workflow — how to use this in a normal day

### 8.1 First thing in the morning (5 minutes)

1. Open the Today page
2. Read the Daily Briefing top-to-bottom — that's your one-sentence team read
3. Scan Decision Summary for RED rows. For each, click to expand and read the Why
4. Check the team outlook band — if "High alert", go deeper before training

### 8.2 Pre-training huddle (10 minutes)

1. Read the **Top Concerns** list aloud to the staff

2. Confirm modifications for any RED player
3. Check **Verdict Accuracy** monthly (not daily) to keep the model honest

### 8.3 Post-training (5 minutes)

1. Click **Post-Training** PDF export
  2. Distribute to head coach + medical team
  3. The next morning the verdicts will reflect today's session — close the loop
- 

## 9. Troubleshooting

### “Several players show **?** but the system said they were **?** yesterday”

The verdict is daily and reflects the latest data. A player can flip RED overnight if last evening's session loaded them heavily, if their morning wellness check-in dropped, or if a new injury was logged. Click the player row and read the Why — the explanation will tell you which signal moved.

### “A player I know is fit shows **?**”

Check the Counterfactual hint underneath. If the system says “*If HRV had been +15, would be GREEN*”, the verdict is being driven by a wellness self-report that may not reflect reality. Talk to the player — sometimes they tap through the check-in without thinking.

If you have eyes-on context the model doesn't, your judgment overrides the model. The Calibration widget tracks how often these overrides match what eventually happened.

### “Decision Summary is empty / showing ‘Insufficient data’ for everyone”

You are likely on a fresh team without 14+ days of data. The system needs at least 14 days of GPS + RPE + wellness check-ins per player to start producing reliable verdicts. The Catapult CSV upload bootstrap (see the Catapult CSV Upload Guide) is the fastest way to get there if your club doesn't have API access.

### “Indoor Briefing isn't showing”

It's conditional — it only renders if your team has recent indoor sessions OR active injuries. If you train exclusively outdoors and have no injury cases right now, it stays hidden. This is intentional — pages should not show empty cards.

### “Forecast / Verdict Accuracy widget not visible”

The Verdict Accuracy widget is hidden until you've accumulated 30+ verdict-actual pairs (about 4–6 weeks of use). The Forecast block in the command center is similarly hidden until 7+ days of streak data per player. Both unlock automatically.

---

## 10. The pages this dashboard sends you to

When a flag on the Today page demands a deeper look, here's where to go:

If you see...

---

Multiple players with high decel flags

Team-wide elevated load

Indoor sessions look spiky

Multiple injured players or RTP questions

A new neuromuscular flag

Concerns about RPE / wellness compliance

Need to plan the next week
